The vortex filament conjecture for Euler flows

We study the evolution of vortex filaments in ideal fluids. A conjecture, dating back to da Rios in 1906, states that if the vorticity is initially concentrated around a closed curve, it remains concentrated for some time and the evolution of the curve is geometrically described by the binormal curvature flow. In a joint work with Bob Jared we focus on the second part of this conjecture and derive the binormal curvature flow under a weak vorticity concentration condition. Our proof relies on estimates for the underlying Hamiltonian structures.
